Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

[0001] This invention relates to syringes and has for its object an autodestruct syringe, that is, one that can be used once only and is rendered disabled by the user during the process of normal use.

[0002] Since the early 1980's the spread of AIDS, Hepatitis and other diseases has partly occurred due to the reusing of syringes. The majority of syringes are of a disposable nature, being easy to manufacture in plastics and are often marked "Use once and destroy". However there is no inbuilt barrier within the product to prevent it from being used more than once and by more than one person.

[0003] Drug abusers have certain ritualistic techniques that must be fully accommodated if an autodestruct syringe design is to be successful and accepted in this vital market segment. Drug abusers can require to insert a needle many times before a suitable injection site is found, and make numerous small insertions and withdrawals during this process. After an injection a user may choose to flush out any drug left in the "dead space" of the syringe with their own blood several times.

[0004] The primary area of concern with the spread of the previously mentioned diseases is that of the drug abuser, but all other areas can benefit from such a syringe, if it in no way hinders the user in the use of it.

[0005] Many attempts have been made to provide such a autodestruct syringe and examples of designs are shown in US-A-4252118, GB-A-2184657, US-A-3478937 and US-A-4367738. However, to date no design has reached the market, either because of complexities in manufacture, or increase in costs. Furthermore earlier designs have not been suitable for the variety of techniques employed by users, in particular the drug abusers, and may not feel "normal" in use.

[0006] Some previous designs have used projection means within the barrel. These however may disrupt the forward motion of the plunger during the injection, and can be "felt" by the user. This is caused by the interaction with the projection means by an elastomeric cap affixed to the plunger.

[0007] Other designs have a breakable means inbuilt to the design so that part of the plunger separates leaving the syringe inoperable. This can be a health risk as it leaves an unprotected piece of broken plastic which has recently been inside a barrel possibly containing contaminated blood. By the removal of part of the plunger the barrel is further exposed to abuse and possible conversion to a working unit. Some previous ideas have only been operable in a syringe with an integrated needle as this protects them from tampering and subsequent reuse.

[0008] Another design is shown in EP-A-0 409 134, which is intended to overcome manufacturing difficulties by having the barrel and the plunger each moulded in one piece. The barrel has two projections which extend into the bore of the barrel by a substantial amount. Each

projection has its distal edge perpendicular to the barrel wall, and a tapered proximal edge. The plunger has a head with an integral seal which locks with a projection to prevent withdrawal of the plunger.

[0009] Therefore the ideal product is one which fits closely in with the current manufacturing techniques and assembly procedures, offers no resistance to the user, and is truly autodestruct so that it cannot be tampered with.

[0010] According to the present invention, a syringe comprises a barrel having a plunger in slidable and sealing engagement therein, in which the barrel has at least one means interrupting a cylindrical surface of its inner wall, and the plunger has a head carrying a seal, and a locking means, the locking means operating on engagement with an interruption means on withdrawal of the plunger to prevent further withdrawal movement, and the locking means being separate from the seal and attached to the head, the construction being such that the barrel is formed as a one-piece moulding, and the plunger with the locking means is also formed as a one-piece moulding.

[0011] The arrangement allows for use of the syringe in a normal way but is rendered unfit for further use after one injection by operation of the locking means. It also has the advantage that it is easy to make with current techniques, as the barrel and the plunger are each a one-piece moulding. In particular, the arrangement of the plunger with a head carrying a seal, and locking means separate from the seal enables the plunger to be made as a one-piece moulding.

[0012] Preferably, an interruption means is arranged adjacent the distal end of the barrel. The distal end is the end to which the needle is attached. It is not possible to withdraw the plunger further than the distal end interruption means once the injection has taken place. The interruption means may be positioned to allow flushing after a full injection, but prevent refilling of the barrel. A further interruption means may be located at the proximal end of the barrel. This prevents removal of the plunger prior to use, which would serve as a total tamper proof feature.

[0013] The interruption means is preferably arranged at an angle other than 90° to the longitudinal axis of the barrel. This allows friction between the plunger and the interruption means to be dissipated as only part of the interruption means is in contact with the plunger at any one moment. The interruption means preferably extends round the whole circumference of the barrel.

[0014] Each interruption means may be a projection. Quite a small projection enables the locking means to operate, and if arranged at an angle will not disrupt the forward motion of the plunger, so that it is not "felt" by the user.

[0015] Preferably however each interruption means comprises a groove. Grooves offer no resistance to the plunger, so that a normal feel to the injection is achieved. They are also more positive in ensuring operation of the

locking means.

[0016] It would also be possible for the interruption means to comprise a groove followed by a projection.

[0017] Angled grooves and projections are much easier to produce by injection moulding than those at right angles to the barrel axis.

[0018] Each projection or groove is preferably of substantially triangular cross-section, with a first edge inclined slightly to the cylindrical surface, and a second edge inclined sharply to the cylindrical surface. The first edge allows normal forward movement of the plunger, while the second edge engages the locking means on withdrawal movement. The first edge is preferably at an angle of between 20° and 30° to the cylindrical surface. The second edge is substantially perpendicular to the first edge, and at an angle of between 60° and 70° to the cylindrical surface.

[0019] Preferably the seal of the plunger comprises an elastomeric sealing cap, and the head of the plunger has means, such as a peg, with which the elastomeric sealing cap engages, and the locking means is attached to the head of the plunger, adjacent the cap. The locking means locks into the interruption means and jams, effectively rendering the syringe useless. Following engagement of the locking means with the interruption means, the locking force increases as the withdrawal force applied to the plunger increases. The plunger seal remains intact, filling the barrel, and acting as an anti-tamper block. If excess effort is applied in the removal direction it may break at the joint between the stem of the plunger rod and head. However, this is not the object of the design as the locking feature is more than adequate to prevent reuse and the more preferable.

[0020] The locking means preferably comprises two rearward facing flukes attached to the head by a flexible connection, movable in each direction but engaging with the interruption means on withdrawal movement away from the distal end of the barrel. When engaging with for example an angled groove the head of the plunger is deflected in the barrel perpendicular to the groove so that both flukes are located in the groove, as far as the flexibility of the connection and the elasticity of the elastomeric cap will permit. Alternatively, the locking means comprises a disc attached to the head, and having a flexible periphery which slides in either direction, but engages with the interruption means on withdrawal movement. It is preferably held by the head in the locked position. The disc may be cross-shaped.

[0021] The design can be incorporated into a syringe product with or without an integrated needle. However the present invention benefits from being tamper proof in an open luer type syringe barrel and in a barrel with an integrated needle.

[0022] The two plastics parts (the barrel and the plunger) are preferably manufactured by injection moulding. The plunger is made with the peg over which the elastomeric cap is fitted to engage and seal with the inner wall of the barrel.

[0023] The plunger is moulded in a traditional mould which can be manufactured to include either of the modifications described. Alternatively a new or existing mould can be fitted with inserts which relate to this fluke/connection or disc area. This means an existing product can be changed to include the modification of this invention for relatively low capital costs. Likewise the barrel described in this invention can be produced through modification of the moulding cores for the barrel, which again is only a fraction of the total capital for such a moulding tool.

[0024] In order that the invention may be more readily understood, embodiments thereof will now be described by way of example, with reference to the accompanying drawings, in which:-

Figure 1 is a side elevation of a syringe constructed in accordance with one embodiment of the invention;

Figure 2 is an end view of the syringe barrel of the syringe in Figure 1 looking from the proximal end;

Figure 3 is a side elevation of the syringe plunger of the syringe in Figure 1;

Figure 4 is an enlarged view of the distal end region of the syringe plunger;

Figure 5 is a cross-section taken along the line V-V of Figure 4 and looking in the direction of the arrows;

Figure 6 is a cross-section taken along the line V1 - V1 of Figure 4 and looking in the direction of the arrows;

Figure 7 is a longitudinal section of the syringe barrel of the syringe in Figure 1;

Figure 8 is a longitudinal section of the distal end region of the syringe barrel, to an enlarged scale;

Figure 9 is a detail view of the groove as shown in Figure 8;

Figures 10 to 13 are cross-sectional side elevations of the syringe showing the plunger in different positions;

Figure 14 is a longitudinal section of the distal end region of the syringe, to an enlarged scale, showing the plunger jammed into the groove in the barrel, this being the unusable state;

Figure 15 is a longitudinal section of the proximal end region of the syringe barrel, to an enlarged scale and showing a modification;

Figure 16 is an alternative design for the syringe plunger distal end;

Figure 17 is a longitudinal section of the barrel which shows the arrangement of grooves in accordance with another embodiment of the invention;

Figure 18 is a side view of a plunger head with a modified locking means;

Figure 19 is a cross-section on the lines X - X of Figure 18;

Figure 20 shows the locking means in the forward movement position; and

Figure 21 shows the locking means in the locked position.

[0025] Referring to Figure 1 and 2 of the drawings the syringe comprises a barrel 1 and a plunger 7. The barrel has an inner cylindrical surface, an open proximal end 2 provided with a gripping flange 3 and a distal end 4 having an internal abutment shoulder 5 encircling a liquid outlet 6. The liquid outlet 6 can be arranged in a variety of ways as needed; the one shown is a luer slip design which holds a needle (not shown) with a friction fit; a luer lock onto which a needle screws; or can be arranged to accept a needle which is affixed permanently by glue, heat or some other means. The syringe plunger 7, shown inserted, comprises a rod 8 and finger plate 9, for gripping the plunger. At the distal end of the rod 8 is an elastomeric sealing cap 15, adjacent to which are formed locking means 17 adapted to engage with means interrupting the cylindrical surface of the inner barrel wall, comprising grooves 10, 11, as explained in more detail below, in order to provide an autodestruct construction.

[0026] As shown in Figures 3 to 6, the plunger 7 has the traditional rod 8 and finger plate 9 used for pushing in and pulling out the plunger. At the distal end the plunger has a head 14 comprising a peg 13 over which is fixed an elastomeric cap 15 which forms a complete seal for liquids and gasses in the barrel 1. The peg 13 has a base 16 which supports the cap 15. On the opposite side of the base 16 is a tubular connection 18 to the plunger rod 8 which forms a strong yet slightly flexible join. Also affixed to the base 16 are two flukes 17, which form the locking means. The flukes are arranged so that their outer radial proximal edges 19 are in contact with the inner barrel wall when assembled. The axial edge can be arranged with a straight edge as in Figure 4 or have an arcuate edge such as shown in Figure 16. The edge 19 may also have a variety of arrangements to best match the grooves in the barrel.

[0027] The flukes 17 project outside the base 16 when viewed in Figure 5 which is a cross-sectional view as shown by the arrows V-V in Figure 4. The base does not

touch the inner wall of the barrel but this drawing shows the arrangement of how the flukes will project and make contact with the barrel wall.

[0028] The position of the connection 18 is shown clearly in Figure 6.

[0029] Figure 7 is a longitudinal section through the barrel showing the position and typical angle of location of the grooves 10, 11. The distal groove 10 is arranged in a suitable position for the use of the syringe. In this example the groove 10 is in a position to allow for aspiration after the full injection stroke of the plunger. This is vital in some syringe use to allow the user to check the needle is still placed within a blood vessel, and/or to allow a drug abuser to flush the drug from the dead space 12 through drawing in and expelling blood. The proximal groove 11 is positioned to allow a complete rearward motion with the plunger, but does not allow the plunger to be removed. This has two advantages: it can be position to indicate when a certain volume of fill with a liquid has been achieved, which can be useful with sight impaired users. Also this groove prevents the removal of the plunger from the barrel once it has been assembled. Therefore the plunger cannot be replaced or tampered with to render the syringe reusable.

[0030] The groove 10 is shown in detail in Figure 8, and in section in Figure 9. The groove 10 extends round the whole of the circumference of the inner wall, and is of substantially triangular cross-section. The groove 10 has a first, distal edge 10' which is slightly inclined, by 20° to 30°, to the inner wall to allow forward movement of the plunger. It has a second, proximal edge 10" more sharply inclined, by about 60° to 70° to the inner wall, to engage the locking means 17 on withdrawal. The first and second edges are substantially perpendicular. The groove 10 is also arranged at an angle other than perpendicular to the longitudinal axis of the barrel 1. This angle, which may be up to 30°, means that on advance of the elastomeric cap 15, the friction felt by the user is not the same as the friction experienced when advancing in and past a groove or projection arranged perpendicular to the barrel axis. The cap 15 meets the proximal edge of the groove 10 first. The elastomeric cap 15 has a leading edge which forms a tight seal with the inner wall of the barrel and exerts a slight outward pressure to achieve this seal. This pressure is only slightly affected when meeting the small area of groove 10 exposed. As the cap 15 moves forward it leaves the primary contact area and moves on and so is only in contact with a small area of change of resistance. This gives a smoother feel to the injection which is very much an advantage for the invention. The proximal groove 11 is similar to the distal groove 10.

[0031] The grooves 10, 11 are very precise in cross-section and are very easy to manufacture in this arrangement. This is an advance from previous inventions, as theoretically it is very difficult to make such a groove in a barrel of one piece. A groove provides a much more solid form of a restrictive means compared

to say a projection means. The advantage for moulding grooves 10, 11 is their angle to the longitudinal axis and the axis of withdrawal by the moulding core. This means the projection from the core which forms the groove is able to pass out of the moulded barrel without disturbing the soft inner wall of the barrel. As shown in Figure 17, the proximal groove 11 can be oriented 180° in axial rotation to the distal groove. This offers less resistance to the moulding core upon withdrawal as the distal projection upon it does not fully locate into the proximal groove 11.

[0032] The operation of the syringe is shown in Figures 10 to 13. The syringe allows for "normal" use. Figure 10 shows the plunger in the position it is supplied in. If the plunger was inserted any further it would be rendered unusable due to the flukes 17 passing to the distal side of the groove 10. There are many additions that can be applied to the product which can prevent premature insertion of the plunger but these are not the subject of this invention. The user fills the syringe by pulling back the plunger as in Figure 11 and is at liberty to fill the syringe to the required level without restrictions. Sometimes a second fill is desired for instance when mixing two liquids in the barrel and this is unhindered. A drug abuser for example will after filling the syringe insert the needle under the skin in an effort to locate a vein suitable for injecting. This action requires retracting the plunger and drawing body fluid into the distal end of the syringe barrel. The colour and quantity of this fluid indicates to the user the suitability of the site. This technique and other are accommodated within the limits of the syringe.

[0033] After the injection stroke the plunger will be in a position as shown in Figure 12. Then if it is required the plunger can be withdrawn a predetermined distance to accommodate aspiration of flushing as it is commonly known, but not further than the groove 10.

[0034] Figure 13 shows the plunger in the position of maximum withdrawal. At this location the flukes will start to engage with the groove 11, which as described above prevents removal of the plunger and any subsequent tampering that could follow.

[0035] When the flukes 17 engage with either groove (10 or 11) it results in an engagement shown clearly in Figure 14. Once the flukes 17 engage with the groove they expand widthways to fill the available space due to the tension moulded into them. This prevents any further rearward movement. The head of the plunger aligns with the angle of the groove as shown and further distorts the normal alignment and so further prevents rearward movement. Furthermore the connection rod 18 touches the rear section of the proximal fluke and so displaces the fluke more outwards and more securely into the groove. The action of the flukes as described acts as a self tightening lock in that the harder the user pulls the plunger in a desire to reuse the syringe the harder it locks itself. If sufficient force is applied the plunger 7 will break at the connection rod 18.

[0036] Figure 15 shows a modification in which the in-

terruption means comprises a projection 29 rather than a groove. The projection 29 is formed as an annulus which is angled to the axis of the barrel 1. The projection 29 is of triangular cross-section. It has a first proximal edge 29' inclined slightly to the inner wall, by between 20° and 30°, to allow forward movement of the plunger. The projection 29 also has a second, distal edge 29", sharply inclined to the inner wall, by about 60° to 70°, to engage the locking means on withdrawal. In use, the projection 29 operates in a similar way to the grooves 10, 11. The flukes 17 pass over the projection 29 on forward movement of the plunger 7, but engage with it on withdrawal movement. The engagement twists the head of the plunger, so that it cannot withdraw further.

[0037] In a further modification (not shown) the interruption means comprises a groove 10 followed immediately on its proximal side by a projection 29. This provides very satisfactory operation of the locking means 17.

[0038] Figures 18 to 21 show a modified locking means. Corresponding reference numerals have been applied to corresponding parts. Instead of the flukes 17, the locking means comprises a flexible cross-shaped disc 20. The disc 20 is connected to the base 16 by a short central connector 21, and the connection 18 is also shortened, and connects the disc 20 to the plunger rod 8. The disc 20 has a tapered periphery 22, which is smaller adjacent the base 16. This arrangement reduces the space taken up by the locking means.

[0039] Figure 18 shows the plunger 7 at rest, while Figure 20 shows the plunger moving forwardly. The periphery of the disc 20 deflects away from the base 16, and the side remote from the base 16 engages the plunger rod 8. The disc 20 is therefore supported, and the tapered periphery 22 becomes substantially parallel to the barrel surface (not shown) so that the plunger 7 slides easily, and passes over the groove 10.

[0040] On rearward or withdrawal movement the periphery of the disc 20 deflects the other way, and engages with the base 16. In this position it can still slide in the barrel 1, but on reaching a groove 10, 11 the outer edge of the tapered periphery 22 enters the groove and forms a shoulder preventing withdrawal movement out of the groove. As the disc 20 is supported on the base 16 the disc 20 cannot deflect further to slide past the groove 10.

[0041] If sufficient force is applied in the locked position, the connection 18 breaks. It may also tend to break inadvertently if the plunger 7 is twisted in normal use. In a modification (not shown), the connection 18 is made larger and the connector 21 smaller in diameter. The connection 18 will then resist the tendency to break on twisting the plunger 7 in normal use. In the locked position, when sufficient force is applied to the plunger 7 the deflected disc 20 acts as a lever on the base 16, so that the connector 21 breaks and the head of the plunger 7 "pops" off.

[0042] The modified locking means are shown engag-

ing with a groove 10 which is at right angles to the barrel axis. It would operate just as well with an angled groove, or with the angled projection 29 of Figure 15.

[0043] The barrel 1 and plunger 7 are made of plastics material, by injection moulding. It will be appreciated that each is a single moulding, thus keeping down the cost of manufacture. In fact, the moulding tools for manufacture of existing plungers (those without the locking means) may be modified to include the locking means.

Claims

1. A syringe comprising a barrel (1) and a plunger (7) in slidable and sealing engagement therein, the barrel (1) having at least one means (10,11;29) interrupting a cylindrical surface of its inner wall, and the plunger having a head (14) carrying a seal, and a locking means (17,20), the arrangement being such that the locking means (17,20) operates on engagement with an interruption means (10,11;29) on withdrawal of the plunger (7) to prevent further withdrawal movement, **characterised in that** the locking means (17, 20) is separate from the seal and attached to the head (14), the construction being such that the barrel (1) is formed as a one-piece moulding, and the plunger (7) with the locking means (17, 20) is also formed as a one-piece moulding.
2. A syringe as claimed in claim 1, **characterised in that** an interruption means (10; 29) is provided adjacent the distal end (4) of the barrel (1).
3. A syringe as claimed in claim 1 or claim 2, **characterised in that** an interruption means (11;29) is arranged at the proximal end (2) of the barrel (1).
4. A syringe as claimed in any preceding claim, **characterised in that** at least one interruption means (10,11;29) extends round the whole circumference of the barrel (1).
5. A syringe as claimed in any preceding claim, **characterised in that** at least one interruption means (10,11;29) is at an angle other than 90° to the longitudinal axis of the barrel (1).
6. A syringe as claimed in any preceding claim, **characterised in that** at least one interruption means (10,11;29) is of substantially triangular cross-section.
7. A syringe as claimed in any preceding claim, **characterised in that** at least one interruption means comprises a projection (29).
8. A syringe as claimed in any of claims 1 to 6, **char-**

acterised in that at least one interruption means comprises a groove (10,11).

9. A syringe as claimed in any of claims 1 to 6, **characterised in that** at least one interruption means comprises a groove (10,11) followed by a projection (29).
10. A syringe as claimed in any preceding claim, **characterised in that** the seal of the plunger comprises an elastomeric sealing cap (15) and the head (14) of the plunger (7) has means with which the elastomeric sealing cap (15) engages, and the locking means (17,20) is provided on the head (14) of the plunger, adjacent the cap (15).
11. A syringe as claimed in any preceding claim, **characterised in that** the locking means (17, 20) is so constructed and arranged that, following engagement of the locking means (17, 20) with an interruption means (10, 11; 29) the locking force increases as the withdrawal force applied to the plunger (7) increases.
12. A syringe as claimed in claim 11, **characterised in that** the locking means comprises two rearward facing flukes (17) attached to the head by a flexible connection (18), and movable in each direction, but engaging with the interruption means (10,11;29) on withdrawal movement.
13. A syringe as claimed in claim 5 and claim 12, **characterised in that** on engagement of the flukes (17) with an interruption means (10,11;29) the head (14) of the plunger is deflected in the barrel to be perpendicular to the interruption means (10,11;29).
14. A syringe as claimed in claim 11, **characterised in that** the locking means comprises a disc (20) attached to the head (14), and having a flexible periphery (22) which slides in each direction, but engaging with the interruption means (10,11;29) on withdrawal movement.
15. A syringe as claimed in claim 14, **characterised in that** the disc (20) is held by the head in the locked position.
16. A syringe as claimed in claim 14 or claim 15, **characterised in that** the disc (20) is cross-shaped.

Patentansprüche

1. Eine Spritze, die einen Kolbenzylinder (1) und einen Kolben (7) umfaßt, der in den Kolbenzylinder (1) gleitend und abdichtend wirkt, wobei der Kolbenzylinder wenigstens eine Einrichtung (10, 11; 29) hat,

- die eine zylinderförmige Oberfläche ihrer inneren Wand unterbricht, und der Kolben einen Kopf (14) hat, der eine Abdichtung trägt, und die Spritze eine Verschlubeinrichtung (17, 20) umfaßt, wobei die Anordnung so ist, daß die Verschlubeinrichtung (17, 20) beim Zusammenwirken mit einer Unterbrechungseinrichtung (10, 11, 29) beim Herausziehen des Kolbens (7) wirkt, um eine weitere Herausziehbewegung zu verhindern, **dadurch gekennzeichnet, daß** die Verschlubeinrichtung (17, 20) von der Abdichtung separiert und am Kopf (14) befestigt ist, wobei die Konstruktion so ist, daß der Kolbenzylinder (1) als ein einteiliges Formteil geformt ist und der Kolben (7) mit der Verschlubeinrichtung (17, 20) auch als ein einteiliges Formteil geformt ist.
2. Eine Spritze nach Anspruch 1, **dadurch gekennzeichnet, daß** eine Unterbrechungseinrichtung (10; 29) angrenzend an das ferne Ende des Kolbenzylinders (1) bereitgestellt ist.
 3. Eine Spritze nach Anspruch 1 oder Anspruch 2, **dadurch gekennzeichnet, daß** eine Unterbrechungseinrichtung (11; 29) am nahen Ende (2) des Kolbenzylinders (1) angeordnet ist.
 4. Eine Spritze nach einem der vorangegangenen Ansprüche, **dadurch gekennzeichnet, daß** sich wenigstens eine Unterbrechungseinrichtung (10, 11; 29) um den gesamten Umfang des Kolbenzylinders (1) erstreckt.
 5. Eine Spritze nach einem der vorangegangenen Ansprüche, **dadurch gekennzeichnet, daß** wenigstens eine Unterbrechungseinrichtung (10, 11; 29) in einem anderen Winkel als 90° zu der Längsachse des Kolbenzylinders (1) liegt.
 6. Eine Spritze nach einem der vorangegangenen Ansprüche, **dadurch gekennzeichnet, daß** wenigstens eine Unterbrechungseinrichtung (10, 11; 29) einen im wesentlichen dreieckigen Querschnitt besitzt.
 7. Eine Spritze nach einem der vorangegangenen Ansprüche, **dadurch gekennzeichnet, daß** wenigstens eine Unterbrechungseinrichtung einen Überstand (29) umfaßt.
 8. Eine Spritze nach einem der Ansprüche 1 bis 6, **dadurch gekennzeichnet, daß** wenigstens eine Unterbrechungseinrichtung eine Nut (10, 11) umfaßt.
 9. Eine Spritze nach einem der Ansprüche 1 bis 6, **dadurch gekennzeichnet, daß** wenigstens eine Unterbrechungseinrichtung eine Nut (10, 11) umfaßt, gefolgt von einem Überstand (29).
 10. Eine Spritze nach einem der vorangegangenen Ansprüche, **dadurch gekennzeichnet, daß** die Abdichtung des Kolbens eine elastomere Abdichtkappe (15) umfaßt und der Kopf (14) des Kolbens (7) Mittel hat, mit welchen die elastomere Abdichtkappe (15) zusammenwirkt, und die Verschlubeinrichtung (17, 20) auf dem Kopf (14) des Kolbens bereitgestellt ist, nahe bei der Kappe (15).
 11. Eine Spritze nach einem der vorangegangenen Ansprüche, **dadurch gekennzeichnet, daß** die Verschlubeinrichtung (17, 20) so konstruiert und angeordnet ist, daß nach einem Zusammenwirken der Verschlubeinrichtung (17, 20) mit einer Unterbrechungseinrichtung (10, 11; 29) die Verschlusskraft ansteigt, während die Herauszieh-Kraft, die auf den Kolben (7) einwirkt, ansteigt.
 12. Eine Spritze nach Anspruch 11, **dadurch gekennzeichnet, daß** die Verschlubeinrichtung zwei rückwärts gerichtete Flossen (17) umfaßt, die durch eine flexible Verbindung (18) an dem Kopf befestigt und in jede Richtung beweglich sind, aber bei einer Herauszieh-Bewegung mit der Unterbrechungseinrichtung (10, 11; 29) zusammenwirken.
 13. Eine Spritze nach Anspruch 5 und Anspruch 12, **dadurch gekennzeichnet, daß** bei dem Zusammenwirken der Flossen (17) mit einer Unterbrechungseinrichtung (10, 11; 29) der Kopf (14) des Kolbens in dem Kolbenzylinder ausgelenkt wird, um rechtwinklig zu der Unterbrechungseinrichtung (10, 11; 29) zu sein.
 14. Eine Spritze nach Anspruch 11, **dadurch gekennzeichnet, daß** die Verschlubeinrichtung eine Scheibe (20) umfaßt, die an dem Kopf (14) befestigt ist und eine flexible Peripherie (22) hat, die in jede Richtung gleitet, aber bei einer Herauszieh-Bewegung mit der Unterbrechungseinrichtung (10, 11; 29) zusammenwirkt.
 15. Eine Spritze nach Anspruch 14, **dadurch gekennzeichnet, daß** die Scheibe (20) durch den Kopf in der Verschlussposition gehalten wird.
 16. Eine Spritze nach Anspruch 14 oder Anspruch 15, **dadurch gekennzeichnet, daß** die Scheibe (20) kreuzförmig ist.

Revendications

1. Seringue comprenant un cylindre (1) et un piston (7) en engagement coulissant et étanche à l'intérieur, le cylindre (1) ayant au moins un moyen (10, 11 ; 29) interrompant une surface cylindrique de sa paroi interne, et le piston ayant une tête (14) portant

- un joint et un moyen de verrouillage (17, 20), l'agencement étant constitué de telle manière que le moyen de verrouillage (17, 20) fonctionne lors de la mise en prise avec un moyen d'interruption (10, 11 ; 29) lors du retrait du piston (7) afin d'empêcher tout nouveau mouvement de retrait, **caractérisée en ce que** le moyen de verrouillage (17, 20) est séparé du joint et attaché à la tête (14), la construction étant faite de telle manière que le cylindre (1) est constitué par un moulage d'une seule pièce, et le piston (7) avec le moyen de verrouillage (17, 20) est également constitué par un moulage d'une seule pièce.
2. Seringue selon la revendication 1, **caractérisée en ce qu'un** moyen d'interruption (10 ; 29) est agencé de manière adjacente à l'extrémité distale (4) du cylindre (1).
 3. Seringue selon la revendication 1 ou 2, **caractérisée en ce qu'un** moyen d'interruption (11 ; 29) est agencé au niveau de l'extrémité proximale (2) du cylindre (1).
 4. Seringue selon l'une quelconque des revendications précédentes, **caractérisée en ce qu'au moins** un moyen d'interruption (10, 11 ; 29) s'étend autour de toute la circonférence du cylindre (1).
 5. Seringue selon l'une quelconque des revendications précédentes, **caractérisée en ce qu'au moins** un moyen d'interruption (10, 11 ; 29) forme un angle autre que 90° par rapport à l'axe longitudinal du cylindre (1).
 6. Seringue selon l'une quelconque des revendications précédentes, **caractérisée en ce qu'au moins** un moyen d'interruption (10, 11 ; 29) présente une coupe transversale sensiblement triangulaire.
 7. Seringue selon l'une quelconque des revendications précédentes, **caractérisée en ce qu'au moins** un moyen d'interruption comprend une saillie (29).
 8. Seringue selon l'une quelconque des revendications 1 à 6, **caractérisée en ce qu'au moins** un moyen d'interruption comprend une rainure (10, 11).
 9. Seringue selon l'une quelconque des revendications 1 à 6, **caractérisée en ce qu'au moins** un moyen d'interruption comprend une rainure (10, 11) suivie par une saillie (29).
 10. Seringue selon l'une quelconque des revendications précédentes, **caractérisée en ce que** le joint du piston comprend une calotte d'étanchéité en élastomère (15), et la tête (14) du piston (7) a des moyens avec lesquels la calotte d'étanchéité en élastomère (15) vient en prise, et le moyen de verrouillage (17, 20) est agencé sur la tête (14) du piston, de manière adjacente à la calotte (15).
 11. Seringue selon l'une quelconque des revendications précédentes, **caractérisée en ce que** le moyen de verrouillage (17, 20) est conçu et agencé de manière à ce que, après la mise en prise du moyen de verrouillage (17, 20) avec un moyen d'interruption (10, 11 ; 29), la force de verrouillage augmente au fur et à mesure que la force de retrait appliquée sur le piston (7) augmente.
 12. Seringue selon la revendication 11, **caractérisée en ce que** le moyen de verrouillage comprend deux pattes orientées vers l'arrière (17) attachées à la tête par une connexion souple (18) et pouvant se déplacer dans chaque direction mais venant en prise avec le moyen d'interruption (10, 11 ; 29) lors du mouvement de retrait.
 13. Seringue selon la revendication 5 et la revendication 12, **caractérisée en ce que**, lors de la mise en prise des pattes (17) avec un moyen d'interruption (10, 11 ; 29), la tête (14) du piston est déviée dans le cylindre de manière à être perpendiculaire au moyen d'interruption (10, 11 ; 29).
 14. Seringue selon la revendication 11, **caractérisée en ce que** le moyen de verrouillage comprend un disque (20) attaché à la tête (14), et ayant une périphérie souple (22) qui coulisse dans chaque direction mais vient en prise avec le moyen d'interruption (10, 11 ; 29) lors du mouvement de retrait.
 15. Seringue selon la revendication 14, **caractérisée en ce que** le disque (20) est maintenu par la tête dans la position verrouillée.
 16. Seringue selon la revendication 14 ou 15, **caractérisée en ce que** le disque (20) a la forme d'une croix.
